FitBuddy

Proposed Solution

A simple AI-assisted web app for creating and refining fitness plans

Solution overview

Build a responsive web application where a user enters basic profile details, a fitness goal, and preferred intensity. The app generates a structured 7-day workout plan and a short supporting nutrition or recovery tip. Users can submit feedback to request a revised plan. Original and updated plans are stored for later review.

How it works

1. User completes a short form with name, age, weight, goal, and intensity.
2. FastAPI validates the submission and sends relevant context to the AI service.
3. Gemini generates the workout plan; a fast model generates a concise supporting tip.
4. The app saves the user and original plan in SQLite, then displays the result.
5. User submits feedback; the app retrieves the original plan and requests a revision.
6. The updated plan is saved separately and shown with the original retained.

Main components

Frontend: HTML, CSS, and Jinja2 templates for the input, result, and admin pages.
Backend: FastAPI routes for form handling, validation, AI calls, and page rendering.
AI: Gemini API for plan generation, feedback updates, and concise tips.
Storage: SQLite and SQLAlchemy for users and plan history.
Runtime: Python and Uvicorn for local development and serving.

First release priorities

1. Input form and validation. 2. Workout generation and results page.
3. Save original plans. 4. Feedback updates and plan history.
5. Nutrition/recovery tip. 6. Restricted coach/admin overview.

Responsible design

Collect only necessary details, protect API credentials, and restrict admin access.
Ask users to consider limitations and stop if an activity causes pain. Present generated content as general fitness guidance, not diagnosis or medical advice.

Expected result

A clear starting routine users can understand, follow, and refine as their preferences change.

Proposed from the supplied FitBuddy project brief; validate requirements and AI output with users.
